The Acene Series: Narrowest Zig-Zag Graphene Nanoribbons

Prof. Dr. Holger F. Bettinger
Institut für Organische Chemie, Auf der Morgenstelle 18, 72076 Tübingen, Germany

Acenes [n]ac, consisting of linearly fused benzene rings, are important materials for organic electronics and are currently in the focus of materials research.\(^1\) Reactivity increases among the acene series significantly with length,\(^2\) causing instability for acenes longer than hexacene.

The acenes beyond hexacene are assumed to be notoriously unstable,\(^3\) but are valuable for studying the transition from stable organic molecules to zig-zag graphene nanoribbons that may be metallic in the limit of infinite length. To allow experimental investigations of larger acenes,\(^4\) we have developed synthetic access to acenes up to undecacene [11]ac.\(^5\) We report on the properties of those higher acenes, in particular with respect to their optical and magnetic properties.
